Volatile memory loses stored data when power is removed. On the other hand, nonvolatile memory retains stored data when power is removed. In a volatile memory system, data stored in memory cells is lost when power is removed. In a nonvolatile memory system, data stored in memory cells is maintained when power is removed. In a read operation, a volatile memory system generally outputs stored data in response to a memory read command in a memory chip. In a nonvolatile memory system, stored data is generally not output in response to a memory read command. However, in a nonvolatile memory system, data stored in the memory cells of the memory chip can be output in response to a memory write command. Generally, nonvolatile memories such as NAND type flash memories, NOR type flash memories, ferroelectric random access memories (FeRAMs), and phase change random access memories (PRAMs) may be used as the nonvolatile memories. In particular, NAND type flash memories are generally widely used due to advantages of high integration density, low cost, low power consumption, and high speed operation. FIG. 1 illustrates a conventional NAND type flash memory cell. Referring to FIG. 1, the conventional NAND type flash memory cell has a stacked gate structure which includes a tunnel oxide layer 12, a floating gate 14, an ONO (Oxide Nitride Oxide) layer 16, and a control gate 18. The conventional NAND type flash memory cell retains stored data by storing charge in the floating gate 14. The conventional NAND type flash memory cell generally uses Fowler- a1d647c40b
