Static and dynamic head-related transfer functions before and after cochlear implantation. Objective measures of speech perception before and after cochlear implantation (CI) may be useful for preoperative counseling and postoperative

evaluation of surgical outcomes. No previous studies have examined the change in head-related transfer function (HRTF) values after CI, using a virtual reality (VR) test paradigm. Forty-eight patients with bilateral CIs were assessed using a VR test paradigm before implantation and after at least 6 months of continuous use of the implant. Simultaneous bilateral HRTF measurements of speech perception were obtained and compared before and after

implantation. In addition, monaural HRTF measurements were obtained in 36 of these patients at preand postoperative time points. Finally, monaural standard score (SS) values were calculated for each patient before and after surgery. After CI, the bilateral and monaural measures of HRTF differed significantly before and after implantation. These measures were significantly better for the implanted ear than the nonimplanted ear, but not
